Sensor Processing

So far, our code looks something like this:

```c
loop()
{
    <read some sensors>
    <respond to the sensor input>
    <read some other sensors>
    <respond to the sensor input>
}
```
Sensor Processing

• Sometimes, this is sufficient
• Other times:
  – We need to respond to certain events very quickly, or
  – We need to time events very carefully
Interrupts

• Hardware mechanism that allows some event to temporarily interrupt an ongoing task

• The processor then executes a small piece of code called: interrupt handler or interrupt service routine (ISR)

• Execution then continues with the original program
Some Sources of Interrupts (atmega2560)

External:
- An input pin changes state
- The UART receives a byte on a serial input

Internal:
- A clock
- Processor reset
- The on-board analog-to-digital converter completes its conversion
Interrupt Example

Suppose we are executing code from your main program:

LDS R1 (A) → PC
LDS R2 (B)
CP R2, R1
BRGE 3
LDS R3 (D)
ADD R3, R1
STS (D), R3
An Example

Suppose we are executing code from your main program:

LDS R1 (A)
LDS R2 (B)
CP R2, R1
BRGE 3
LDS R3 (D)
ADD R3, R1
STS (D), R3
An Example

Suppose we are executing code from your main program:

LDS R1 (A)
LDS R2 (B)
CP R2, R1 → PC
BRGE 3
LDS R3 (D)
ADD R3, R1
STS (D), R3
An Example

An interrupt occurs (EXT_INT1):

LDS R1 (A)
LDS R2 (B)
CP R2, R1  → PC
BRGE 3
LDS R3 (D)
ADD R3, R1
STS (D), R3
An Example

Execute the interrupt handler

LDS R1 (A)

PC
Interrupt Service Routines

Generally a very small number of instructions

• We want a quick response so the processor can return to what it was originally doing

• No delays or waits in the ISR…
Timer-Based Interrupts

• Interrupt source: internal hardware timer
• This allows us to produce an interrupt at some regular period

• The exact mechanism is different depending on the type of processor you are using (even if you are using the Arduino environment)
“Timer1” is one predefined variable that can be configured to handle timer operations. Key ones include:

- `Timer1.initialize(usec)`: initialize the timer and set its period
- `Timer1.attachInterrupt(func)`: configure the timer to execute `func` once every period
- `Timer1.start()`: start running the timer
#include <TimerOne.h>

void myISR()
{
    GPIOC_PDOR ^= 0x20;
}

void setup() {
    // Configure PORTC, bit 5 to be a digital I/O bit
    PORTC_PCR5 = PORT_PCR_MUX(0x1);
    // Configure bit 5 to be an output
    GPIOC_PDDR = 0x20;

    // Configure the timer
    Timer1.initialize(200000);
    Timer1.attachInterrupt(myISR);
    Timer1.start();
}

void loop() {
}

What does this program do?
Timer Example

- `myISR()` is called every 200 ms
- Each call to this function flips the state of the built-in LED
- So: the LED flashes at 2.5 Hz

- Note that this happens even though `loop()` does nothing!
  - The ISR executes asynchronously from `loop()`
void myISR() {
    static uint8_t counter = 0;
    ++counter;
    if(counter == 5) {
        GPIOC_PDOR ^= 0x20;
        counter = 0;
    }
}

void setup() {
    PORTC_PCR5 = PORT_PCR_MUX(0x1);
    GPIOC_PDDR = 0x20;

    // Configure the timer
    Timer1.initialize(200000);
    Timer1.attachInterrupt(myISR);
    Timer1.start();
}

void loop() {
}

What does this program do?
Timer Example II

• LED flips state once every fifth call to the ISR
• So: the flashing frequency is $2.5/5 = 0.5$ Hz
Timer1 Notes

Timer1 is used within the Arduino Environment to handle `analogWrite()` for pins 3 and 4 (for the Teensy 3.5)

- By using the timer, `analogWrite()` will no longer function
- Instead, you can use: `Timer1.pwm(pin, duty)` to configure PWM for pins 3 and 4
- And `Timer1.setPwmDuty(pin, duty)` to change the duty cycle
- Note duty = [0 … 1023]
Timer1: Other Functions

- `Timer1.stop()`: stop the timer
- `Timer1.resume()`: continue the timer
- `Timer1.restart()`: start the timer at the beginning of the period
- `Timer1.detachInterrupt()`: turn off the ISR
Timer3

Timer3 behaves the same way as Timer1
• Arduino pins 29 & 30 on the Teensy 3.5
Controlling LED Brightness

What is the relationship of current flow through an LED and the rate of photon emission?
Controlling LED Brightness

What is the relationship of current flow through an LED and the rate of photon emission?

• They are linearly related (essentially)
Controlling LED Brightness

Suppose we pulse an LED for a given period of time with a digital signal: what is the relationship between pulse width and number of photons emitted?
Controlling LED Brightness

Suppose we pulse an LED for a given period of time with a digital signal: what is the relationship between pulse width and number of photons emitted?

• Again: they are linearly related (essentially)

• If the period is short enough, then the human eye will not be able to detect the flashes
Timer Example III

• Problem: implement an ISR that generates a PWM signal
• The duty cycle is determined by the state of a global variable ("duty")
Timer Example III

volatile uint8_t duty = 0;

void loop() {
    for(int i = 0; i < 255; ++i) {
        duty = i;
        delay(10);
    }
    for(int i = 255; i > 0; --i) {
        duty = i;
        delay(10);
    }
}

What is the ISR implementation?
void setup() {
    PORTC_PCR5 = PORT_PCR_MUX(0x1);
    GPIOC_PDDR = 0x20;

    // Configure the timer
    Timer1.initialize(100);
    Timer1.attachInterrupt(myISR);
    Timer1.start();
}

Timer Example III

```c
void myISR()
{
    // PORTC, bit 5
    static uint8_t counter = 0;
    ++counter;
    if(counter == 0)
        GPIOC_PDOR |= 0x20;
    if(counter >= duty)
        GPIOC_PDOR &= ~0x20;
}
```
Timer Example III

```c
void myISR()
{
    static uint8_t counter = 0;
    ++counter;
    if(counter < duty)
        GPIOC_PDOR |= 0x20;
    else
        GPIOC_PDOR &= ~0x20;
}
```
Many Challenges to Building Robust Systems
Coding Challenges

Getting embedded code right is hard
• Complex interaction of many pieces
• We often have to test in the real-time context
  – Limited ability to “see” the state of our program
  – A bug can only occur in a very specific situation that only comes up rarely
Coding Challenges

In practice, it is very difficult to write a program that behaves appropriately in all situations

• In some cases: the program produces incorrect behavior (completely or in part), but continues to execute

• In other cases: the program might “lock-up” and cease to execute critical pieces of code
System Degradation over Time

With use, an embedded system can degrade due to mechanical or electrical variation (or interaction with high-energy particles)

- Electrical connections between components can be broken
- Components can fail
- Memory can be corrupted
Corruption of Memory

Software rot: small changes are made to the program at the machine code level
• Introduces subtle bugs that can lead to incorrect behavior or processor lock-up

Permanent data storage corruption:
• EEPROM might store parameters that affect behavior (e.g., \(K_p\) & \(K_v\))
• Corruption also leads to incorrect behavior
Reducing Problems

Proper mechanical stability

- Appropriate choice of connection between components (this includes soldering)
- Strain relief of wires
- Mechanisms to reduce the sensitivity to vibration
Reducing Problems

Proper housing

• Keep contaminants out of the electronics
• Shield from high-energy particles
• Physical protection
Reducing Problems

Proper electrical stability

- Some components require power supplies to be very clean (very little variation in supplied voltage)
- Some components (e.g. motors) can cause a lot of noise on the power supply
- Electrical isolation is often necessary
  - We do this on the hovercrafts!
Mitigation in the Long Term

Program and data corruption:

• Processors need some way to restore their state to a “factory configuration”

• Most often: a human maintainer will need to “reflash” the memories stored in EEPROM

• But: some systems can autonomously detect when corruption occurs and take steps to correct the corrupted memory
Mitigation in the Short Term

Mission critical systems: build in redundancies

- Multiple copies of a sensor or actuator
- Multiple processors, all performing the same functions (in some cases, the processors are executing different implementations of the same code)
  - Subsystems are responsible for comparing the results across the different copies and choosing which to believe
  - Errors can be detected very quickly, and the embedded system can take appropriate corrective measures
Mitigation in the Very Short Term

System lock-ups

• In most embedded systems, we expect certain tasks to be executed at certain rates

• However, a bug in the code can result in a full stop of the program or in an infinite loop for a condition that is never met

• Must avoid these situations in mission-critical systems
Watch-Dog Timers

Solution requires both hardware and software components
Watch-Dog Timers

Hardware solution:

• A short term counter attached to the system clock
• Compare the counter against some fixed threshold, raising an interrupt when they are equal
Watch-Dog Timers

Software component:

• Main program: “feed the dog” periodically by the resetting the counter

• If the “dog is not fed” in a specified duration, then the Interrupt service routine is called
  – ISR can use knowledge of the system to attempt a recovery or identify where an error occurs
Watchdogs in the Teensies

Initialization:

• Register ISR:

```c
extern void isr_function();
:
wdt_isr(isr_function);
```

• Declare watchdog timeout period:

```c
wdt_enable(WDT0_2S);
```

Note: Exact implementation will depend on the processor
Watchdogs in Practice

Use:

• Always execute:
  
  \texttt{wdt\_reset();}

  within the watchdog period

• If the dog is not fed in time, the ISR function will be called. It can:
  – Clean up after the error
  – Store data for later reporting of the error
  – Reboot the processor
Dealing with Unstable Power Supplies

An unstable power supply can throw a processor into a strange, inconsistent state

• At this point, the results from executing individual instructions can be very uncertain

• Would like the processor to protect itself in these situations
Mitigating Unstable Power Supplies

A common solution: Brown-Out Detection circuitry

• At minimum, will force a clean reset of the processor before the power supply voltage drops below a critical level
• In some architectures, the processor can be configured to raise an interrupt following a brown-out
Mitigating Unstable Power Supplies

The brown-out interrupt can:

• Save critical variables to longer-term storage (EEPROM or SSD)
• Configure components for safe shutdown
• Shutdown the processor until power is restored
